Situs Inversus

...Why don't the 9+0 Nodal Cilia MOVE?

# Why our hearts are on left?

---

- Left side is determined at the early stage of development.
  - In some genetic diseases, patients have their hearts on right.
  - In Kartagener's syndrome, immotile cilia in airway epithelium and immotile sperm are linked to right heart.
-

# Motile cilia are necessary for the L-R axis determination.

---

Randomization of the L-R axis in

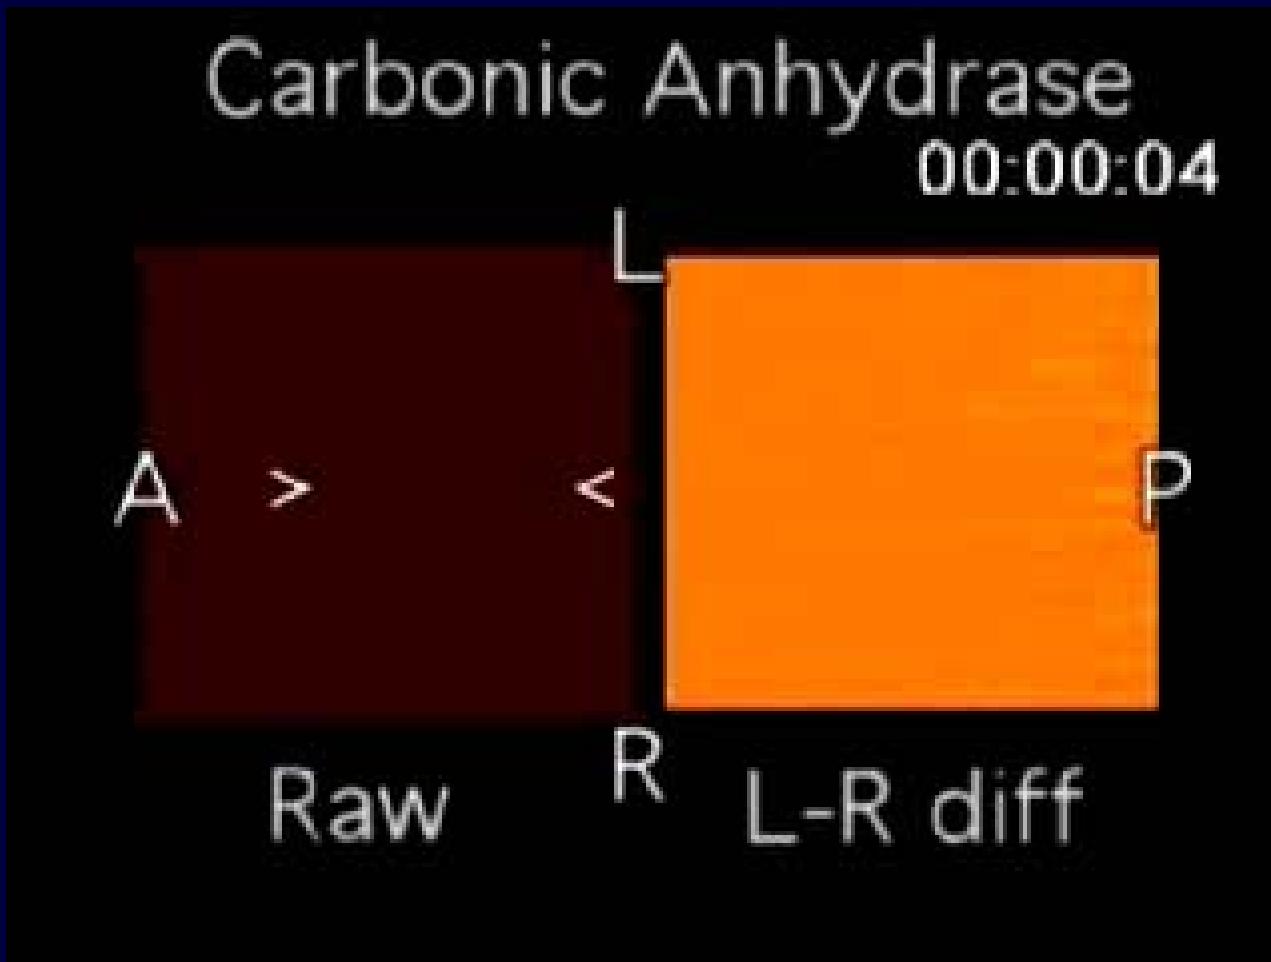

- 1) immotile cilia syndrome (human)
- 2) ciliogenesis mutant mice ( $KIF3^{-/-}$ )

Where are the motile cilia?

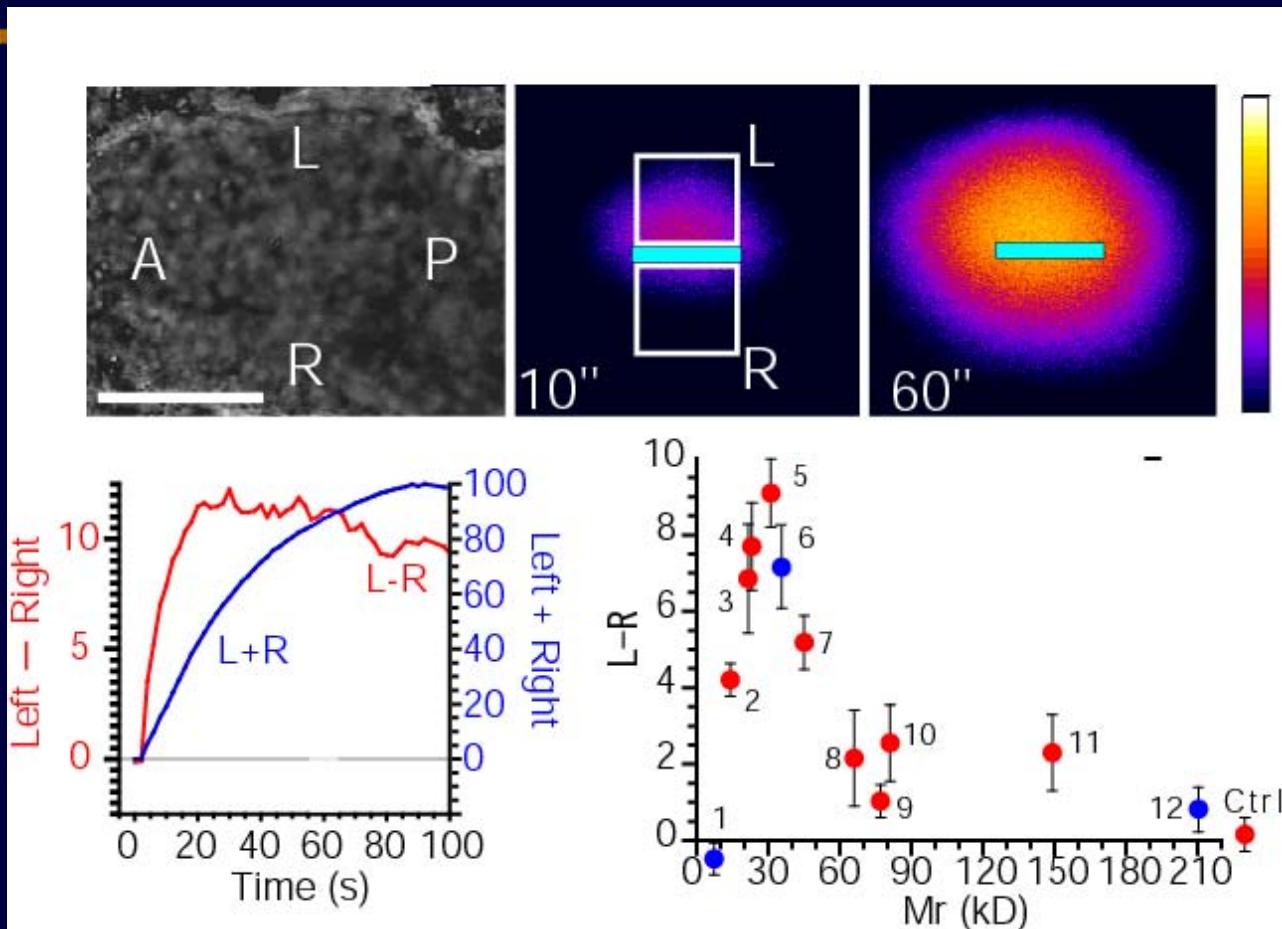

How does the ciliary movement determine the L-R axis?

---

Asymmetric distribution of caged-fluorescently labeled protein after continuous uncaging at the middle of node.

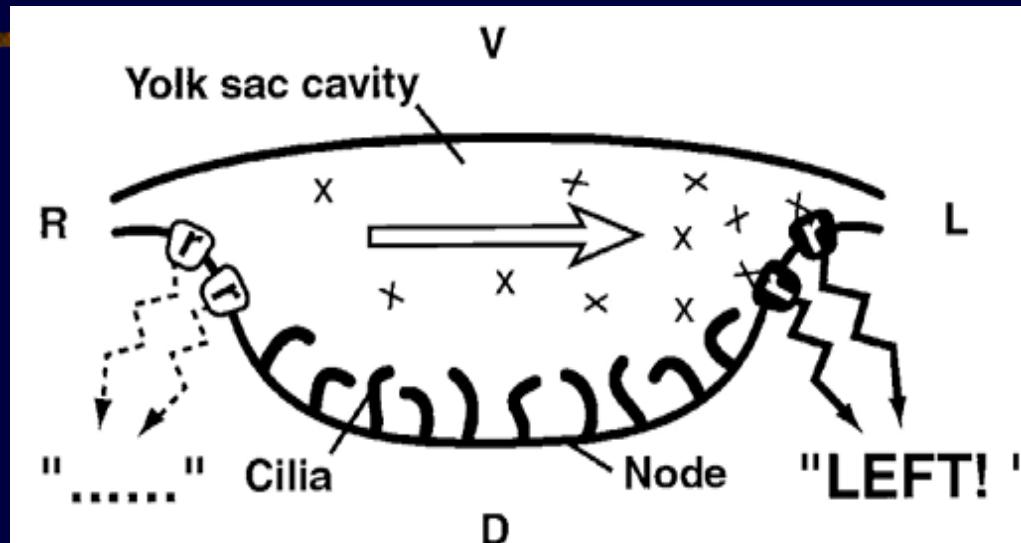

# Asymmetric distribution of 20~40 kDa protein by nodal flow

Leftward nodal flow is rapid enough to generate stationary asymmetric distribution of soluble protein in the node.

# Nodal Flow Hypothesis

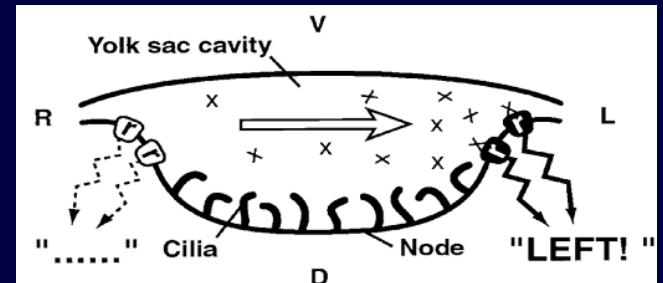

1. Clockwise rotation of cilia
2. Rapid leftward flow
3. Left-specific gene expression

# Is nodal flow universal?

Mouse:

egg cylinder

nodal pit on the ventral surface

Higher vertebrates:

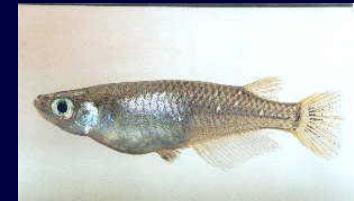

embryonic disc

No nodal pit

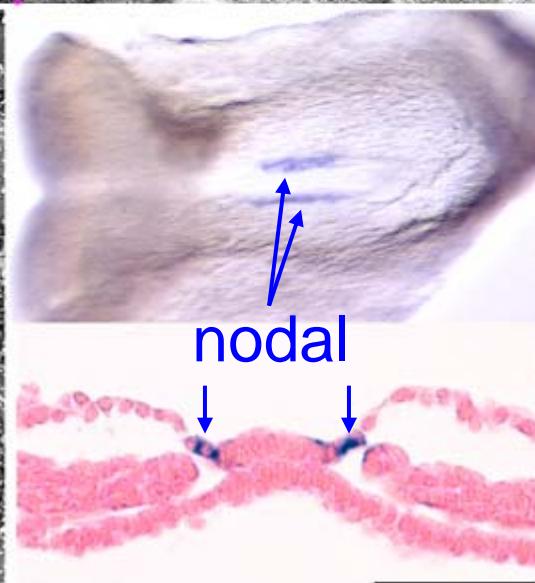

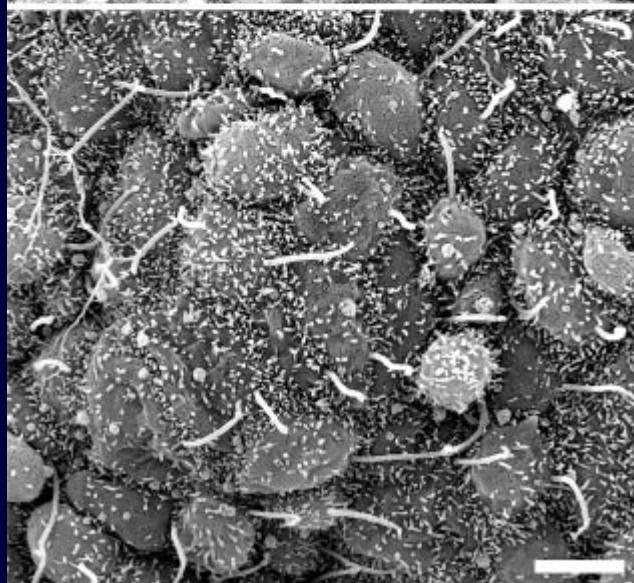

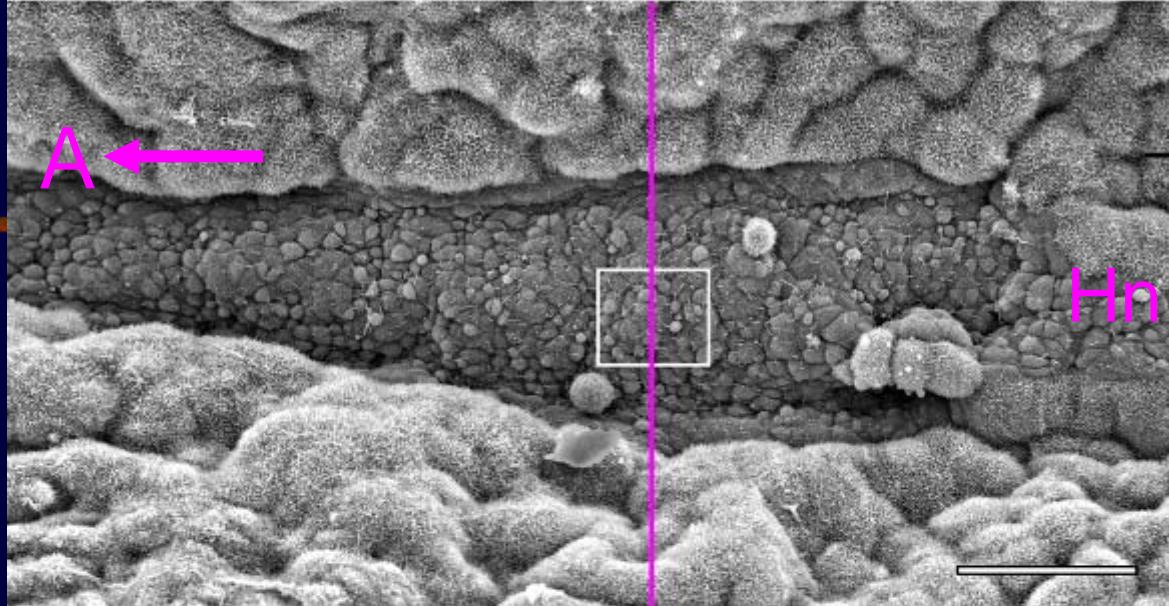

Lower vertebrates:

ventral surface is embedded

# Leftward Flow in the Ventral Node

Conserved:

- Primary monocilia
- Clockwise rotation
- Leftward flow

Not conserved:

- Shape, size and position of the ciliated organ
- Velocity of the flow

# The Nodal Flow Hypothesis

---

1. Leftward Nodal Flow
2. Left-specific expression of master genes
3. Left/right asymmetric morphogenesis

Tautology!

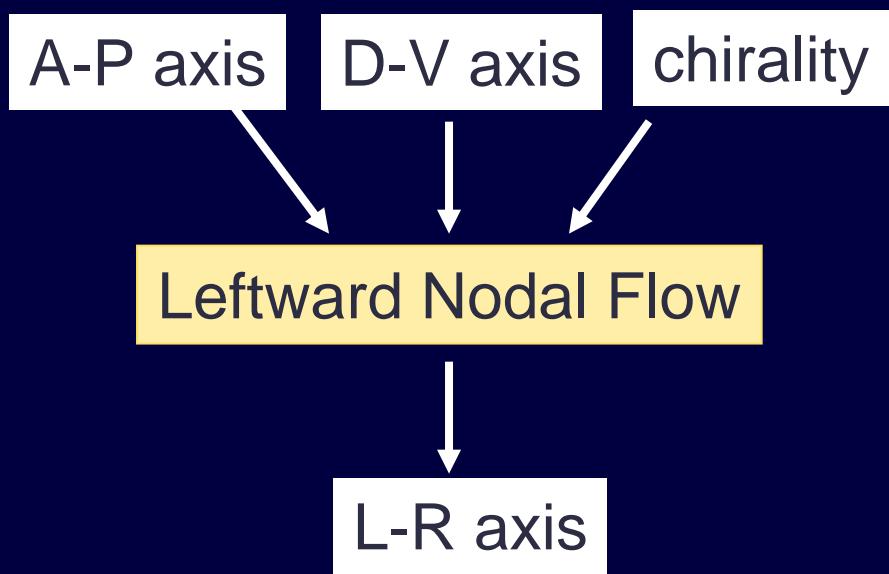

Doesn't answer why left is left.

---

# Central Question:

## What directs the flow to the left?

---

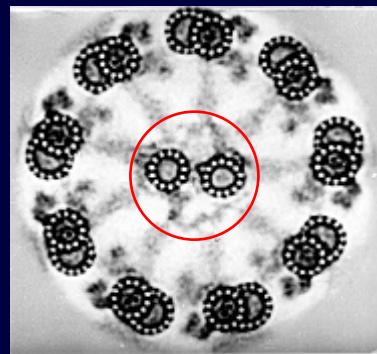

- How are the information of the A-P axis, D-V axis and the chirality integrated to determine the directionality of the nodal flow?
-

# What produces the leftward flow?

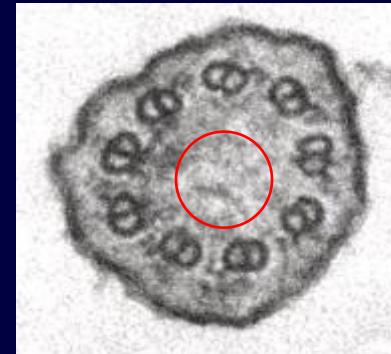

- Rotation of the primary cilia in the node.

Conventional “9+2” cilia

Regulation by the central pair microtubules enables the planar beating.

Primary “9+0” cilia in the node.

No central pair microtubules  
→ unable to beat  
→ Clockwise rotation

# What produces the leftward flow?

---

- Rotation of 9+0 cilia
- Rotation can only produce vortices.
- In *inv* mutant mice, and in the wild type embryos at the earlier stages, the flow is vertical and the leftward flow is not evident.

Some mechanism(s) exist for the conversion into the laminar leftward flow.
